Protein folding mechanism biochemistry - Protein folding mechanism biochemistry 21 minutes - This lecture explains about the **protein**, folding mechanism. The **protein**, folding is most important to form an active site that is used ...

We begin with only the amino acid chain in a random coil. The sequence of amino acids constitutes the primary 1st protein structure. From here, the strand will fold, coil and bend to form more complex secondary (2nd) structures, which may or may not include disulfide bonding

A strand will continue to coil and uncoil until a 2nd configuration is found from which the protein can continue down the folding pathway. This productive configuration will then begin folding in on itself

At this point, the tertiary (3rd) structure is clear, and the protein subunit can only become more complex by association with another protein subunit.

As discussed previously, the two subunits will associate so that their hydrophobic regions are opposite each other. Polar interactions, ionic interactions and other protein side-chain interactions can also stabilize the subunits (refer to enzyme binding for detailed discussion).

The final two subunit protein is shown below. The orientation of the different subunits constitutes the quaternary (4th) structure. Press play to see a diagram of the entire folding process.
